# Becker Lab2

#### Kate Becker

## 1/18/2024

Today we will be continuing the pumpkin case study from last week. We will be using the data that you cleaned and split last time (pumpkins\_train) and will be comparing our results today to those you have already obtained. Open and run your Lab 1.Rmd as a first step so those objects are available in your Environment.

## Lab 1 required for accessing data and varaiables

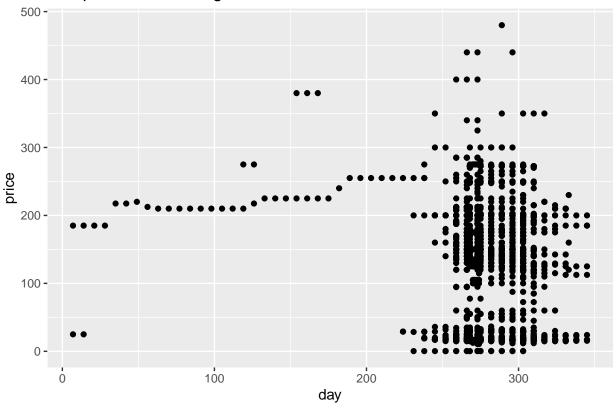

```
#Load required packages and read in data
library("tidymodels")
## -- Attaching packages ------ tidymodels 1.1.1 --
## v broom
              1.0.5 v recipes
                                    1.0.8

  # Overlay a line of best fit
  geom_line(aes(y = .pred), color = "orange", linewidth = 1.2) +
  xlab("package")
```

Once you have done that, we'll start today's lab by specifying a recipe for a polynomial model. First we specify a recipe that identifies our variables and data, converts the package variable to a numerical form, and then adds a polynomial effect with step poly()

### Lab 2

```
# Specify a recipe
poly_pumpkins_recipe <-
recipe(price ~ package, data = pumpkins_train) %>% #specfies a recipe that identifies variables and d
step_integer(all_predictors(), zero_based = TRUE) %>% #converts package variable to a numerical form
step_poly(all_predictors(), degree = 3) #adds a polynomial effect
```

How did that work? Later we will learn about model tuning that will let us do things like find the optimal value for degree. For now, we'd like to have a flexible model, so we'll use a relatively large value.

Polynomial regression is still linear regression, so our model specification looks similar to before.

```
# Create a model specification called poly_spec
poly_spec <- linear_reg() %>%
  set_engine("lm") %>%
  set_mode("regression")
```

Question 1: Now take the recipe and model specification that just created and bundle them into a workflow called poly df.

## Linear Regression Model Specification (regression)
##
## Computational engine: lm

##

## -- Model -----

#step\_integer creates a specification of a recipe step that will convert new data into a set of integer #creates specification of a recipe step that will create new columns that are basic expansions of varia

Question 2: fit a model to the pumpkins\_train data using your workflow and assign it to poly\_wf\_fit

```
## 2 Recipe Steps
##
## * step_integer()
## * step_poly()
##
## -- Model ------
##
## Call:
## stats::lm(formula = ..y ~ ., data = data)
## Coefficients:
     (Intercept) package_poly_1 package_poly_2 package_poly_3
##
          27.97
                       103.86
                                   -110.91
                                                  -62.64
# Make price predictions on test data
poly_results <- poly_wf_fit %>% predict(new_data = pumpkins_test) %>%
 bind_cols(pumpkins_test %>% select(c(package, price))) %>%
 relocate(.pred, .after = last_col()) #.pred precits values based on input data
# Print the results
poly_results %>%
 slice_head(n = 10)
## # A tibble: 10 x 3
##
     package price .pred
##
       <int> <dbl> <dbl>
          0 13.6 15.9
## 1
## 2
          0 16.4 15.9
## 3
          0 16.4 15.9
## 4
         0 13.6 15.9
         0 15.5 15.9
## 5
## 6
         0 16.4 15.9
## 7
         2 34
                 34.4
## 8
          2 30
                 34.4
## 9
          2 30
                  34.4
## 10
          2 34
                  34.4
Now let's evaluate how the model performed on the test_set using yardstick::metrics().
```

```
#smaller rmse, rsq, and mae all prove the model to be better
#mean absolute error
#yardstick works to estimate one or more common performance estiamtes depending on the class of truth
```

Question 3: How do the performance metrics differ between the linear model from last week and the polynomial model we fit today? Which model performs better on predicting the price of different packages of pumpkins?

Compared to the linear model from last week, the polynomial we fit today minimized rmse and mae and maximized rsq clear indicators that this model best fits our data. When applied to our data, the RMSE here implies that on average, this model mispredicts the expected price of different packages by about 328 dollars compared to 722 dollars as observed after using the linear regression. In terms of r-squared, the polynomial model has a much larger R^2, 0.89 compared to 0.49, showing a stronger proportion of the variance in pumpkin price predicted from package type using the polynomial regression. Finally, in terms of MAE, the mean absolute difference between the actual and predicted values is minimized in the polynomial regression and can therefore better predict the price of different packages of pumpkins. In conclusion, the polynomial model does a better job at predicting the price of different packages of pumpkins as seen by the performance metrics.

Let's visualize our model results. First prep the results by binding the encoded package variable to them.

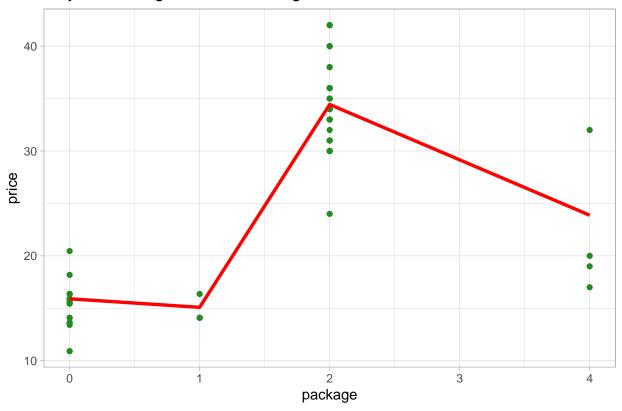

```
## # A tibble: 5 x 4
##
     package package_integer price .pred
##
       <int>
                       <int> <dbl> <dbl>
## 1
                           0 13.6 15.9
           0
## 2
           0
                              16.4 15.9
## 3
           0
                              16.4 15.9
                           0
           0
## 4
                              13.6
                                    15.9
## 5
           0
                              15.5
                                    15.9
```

OK, now let's take a look!

Question 4: Create a scatter plot that takes the poly\_results and plots package vs. price. Then draw a line showing our model's predicted values (.pred). Hint: you'll need separate geoms for the data points and the prediction line.

```
# Make a scatter plot
poly_results %>%
    ggplot(aes(x = package, y = price)) +
    geom_point(color = "forestgreen") +
    geom_line(aes(y = .pred), color = "red", linewidth = 1.2) +
    ggtitle("Polynomial Regression of Package vs. Price")
```

You can see that a curved line fits your data much better.

## 'geom\_smooth()' using formula = 'y ~ x'

Question 5: Now make a smoother line by using geom\_smooth instead of geom\_line and passing it a polynomial formula like this: geom\_smooth(method = lm, formula =  $y \sim poly(x, degree = 3)$ , color = "midnightblue", size = 1.2, se = FALSE)

```
# Make a smoother scatter plot

poly_results %>%
    ggplot(aes(x = package, y = price)) +
    geom_point() +
    geom_smooth(method=lm, se=FALSE) +
    geom_smooth(method = lm, formula = y ~ poly(x, degree = 3), color = "midnightblue", size = 1.2, se = 1.2

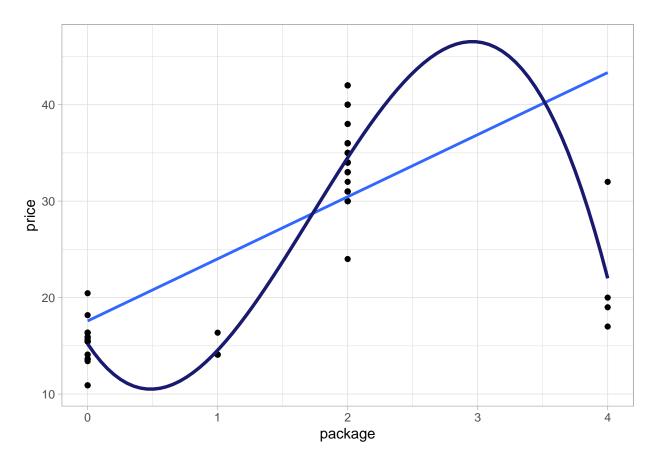

## Warning: Using 'size' aesthetic for lines was deprecated in ggplot2 3.4.0.

## i Please use 'linewidth' instead.

## This warning is displayed once every 8 hours.

## Call 'lifecycle::last_lifecycle_warnings()' to see where this warning was

## generated.
```

# view poly\_results df and class of package and price variables
View(poly\_results)
class(poly\_results\$package)

## [1] "integer"

class(poly\_results\$price)

#### ## [1] "numeric"

OK, now it's your turn to go through the process one more time.

Additional assignment components : 6. Choose a new predictor variable (anything not involving package type) in this dataset. - City\_name

7. Determine its correlation with the outcome variable (price). (Remember we calculated a correlation matrix last week)

#find correlation between city\_name predictor variable and price response variable cor(baked\_pumpkins\structure, baked\_pumpkins\structure)

#### ## [1] 0.3236397

The correlation between the predictor variable (city\_name) and the outcome variable (price) is 0.324 approximately.

- 8. Create and test a model for your new predictor:
- Create a recipe
- Build a model specification (linear or polynomial)
- Bundle the recipe and model specification into a workflow
- Create a model by fitting the workflow
- Evaluate model performance on the test data
- Create a visualization of model performance

### Testing the Linear Model

```
#random number generator
set.seed(123)
# Split the data into training and test sets
